ERP for B2B Furniture Retail: What It's Supposed to Do & How E2GO Maps to That Ideal

Executive Summary

An ERP (Enterprise Resource Planning) system is the authoritative operational backbone of a business — one coherent model of customers, orders, inventory, procurement, fulfillment, and money, with a full audit trail of every significant action. For a B2B furniture retailer operating a dropship model with multiple vendors, that backbone needs to handle an exceptionally complex set of workflows: long lead times, volatile freight costs, multi-vendor basket splitting, configure-to-order SKU variants, freight tier logistics (white glove, inside delivery, etc.), and B2B account management with credit terms and tax exemptions.[1][2] [3][4]

What follows is a domain-by-domain breakdown of what an ERP is supposed to provide for this kind of client, followed by a precise mapping of what the e2go SQL system actually implements across its three core databases.

Part 1: What ERP Software Is Supposed to Provide

The Core Concept: One System of Record

The founding purpose of an ERP is to serve as the **single source of truth (SSOT)** — the one place where operational data is first created, subsequently maintained, and read back by all downstream functions. Before ERP, companies operated with departmental silos: sales in one spreadsheet, purchasing in another, accounting in a third. The fundamental promise of ERP is eliminating that fragmentation so that when an order is placed, every related function — inventory, procurement, fulfillment, finance, customer service — instantly operates from the same authoritative record.[3][5]

An ERP answers **"what happened"** — it is the system of record for core transactions: orders, invoices, payments, and inventory movements. Its value is data integrity, audit trails, and regulatory compliance. Separate analytics layers (data warehouses, BI tools) can sit on top, but they read from the ERP's clean, transactional truth.[^4]

Domain 1: Customer & Commercial Order Management

For a B2B operation, the commercial order layer is far more complex than consumer retail. An ERP must support:[^6]

- **B2B account model**: Business customers are not anonymous shoppers. They have accounts with history, credit status, assigned sales reps, and negotiated pricing. The ERP must maintain a persistent customer master separate from individual orders.

- **Bill-to vs. Ship-to separation**: A corporate customer might bill to headquarters but ship to 15 different job sites or stores. The ERP must model both independently and link them correctly on every order.
- **Pricing tiers and account-level pricing**: B2B pricing is rarely one-size-fits-all. Volume discounts, account-specific contracts, MAP (minimum advertised price) floors, and cost/list/sell price layers must be maintained and applied automatically at order entry.[^6]
- **Credit terms and payment management**: B2B transactions run on terms — Net 30, Net 60, Net 90, or pay-in-advance for new accounts. The ERP must track term graduation, credit limits, outstanding balances, and flag orders that exceed credit exposure. This differs from retail: the ERP facilitates the commercial relationship, not just a single payment event.[7][8]
- **Quote → Order conversion**: B2B sales typically begin with a quote. The ERP should maintain quotes as separate records that convert to orders without re-entry, preserving pricing, line items, and notes through the transition.[^9]
- **Tax exemption management**: Many B2B buyers — government agencies, resellers, nonprofits — are tax-exempt. The ERP must store exemption certificates, apply them at order entry, and handle retroactive exemption corrections.[^10]
- **Order status visibility**: B2B customers expect to know exactly where their order is at any given moment. The ERP must maintain a structured status lifecycle (pending, confirmed, backordered, in transit, delivered, invoiced, closed) with full transition history.[11][12]

Domain 2: Product Information Management (PIM/Catalog)

Furniture has one of the most complex product data models in retail. A single furniture "item" is actually a configurable product with dozens of child SKUs:[^2]

- **Item / SKU hierarchy**: The catalog has a parent item (e.g., "Westfield Sofa, Model 2200") and child SKUs defined by variant axes — fabric, color, wood finish, size, configuration. Each combination is a distinct orderable unit (ItemOption / SKU) with its own lead time, availability, and pricing.[13][1]
- **Lead times per SKU**: This is critical in furniture. A standard SKU ships in 2 weeks; a custom-fabric version ships in 12 weeks. Lead times must live at the SKU level, not just the item level, and must flow through to customer-facing promise dates.[^2]
- **Vendor linkage**: Every item traces back to a supplying vendor. The ERP must maintain this link so procurement, dropship routing, and cost calculations can be done automatically. An item's vendor can change (replacement sourcing, discontinued items), so history matters.[^13]
- **Collections and merchandising groupings**: Furniture sells in collections — "the Westfield Living Room Collection" — where customers buy coordinated pieces. The ERP should model collection membership so cross-sell, inventory bundling, and vendor batch ordering are possible.[^13]
- **Availability signals**: "In stock," "back-ordered until [date]," "discontinued," "estimate in-stock date" — these signals must live in the catalog and propagate to orders and customer communications.[14][1]

- **Rich product content**: Images, attribute values, marketing bullets, specifications (dimensions, weight, materials) — all must live in the same system so product data doesn't fragment into a separate spreadsheet or CMS that falls out of sync with operational data.[^15]

Domain 3: Multi-Vendor Fulfillment & Dropship

This is the single most operationally complex domain for a B2B furniture dropshipper and the area where most generic ERPs struggle:[^2]

- **Order-to-vendor splitting**: A single customer order typically contains items from multiple vendors (e.g., sofa from Vendor A, dining table from Vendor B). The ERP must automatically split the order into vendor-specific fulfillment groups — one per vendor — because each vendor receives its own PO and manages its own shipment independently.
- **Vendor Order / Vendor Line Item model**: Below the customer order header, the ERP needs a vendor grouping layer (VendorOrder) and individual vendor line items (VendorOrderDetail). This is distinct from the customer's line item view because the vendor needs to see only its portion of the order, with its own pricing (cost, not sell), its own ship date, and its own status.
- **Purchase Order generation**: From each vendor group, a Purchase Order (PO) must be generated and transmitted to the vendor. This PO represents the financial commitment to pay the vendor. It carries the vendor's SKU, quantity, cost price, expected ship date, and delivery address.[16][14]
- **Ship date management and revisions**: Furniture vendors routinely revise ship dates — material delays, production backlog, freight congestion. The ERP must track the original promised ship date, every subsequent revision, and the final actual ship date. Without this history, there is no basis for vendor accountability.[^2]
- **Vendor fulfillment status**: Each vendor's portion of an order has its own status lifecycle — pending PO, PO sent, in production, shipped, delivered, invoiced. Operations teams need to view this broken down by vendor across the entire order book.[1][13]
- **Exception management**: The ERP's daily operational cadence in furniture dropship revolves around exceptions — invoices missing ship dates, open orders without POs, orders missing tracking past a threshold, lateships. A production ERP must surface these programmatically, not require humans to manually inspect each order.[^2]
- **Freight and delivery type modeling**: Furniture freight is not a simple "standard shipping" label. It involves freight carriers, accessorial charges (liftgate, inside delivery, white glove, stair carry), delivery zones, and special logistics requirements for heavyweight items. These must be modeled at the order and vendor-order level.[^1]
- **Replacement and cancellation tracking**: Furniture orders get cancelled, replaced, and returned. The ERP must maintain this history — not just delete records — so operations can trace why an order ended and what replaced it.

Domain 4: Procurement & Vendor Relationship Management

Beyond executing individual POs, an ERP provides a structural view of the vendor relationship:[17][18]

- **Vendor master**: Each vendor has a profile — contact information, lead time norms, payment terms, discount schedules, performance history. This is the foundation for all vendor interactions.
- **PO lifecycle**: From creation through vendor acknowledgment, shipment, receipt, and invoice matching. A complete PO lifecycle means the ERP knows not just that a PO was sent but whether it was acknowledged, whether goods arrived, and whether the invoice matches.
- **Vendor performance metrics**: On-time delivery rate, average lead time accuracy, quality/damage rates, cost trend. These KPIs can only be calculated if the ERP stores both the promised and actual data on every PO line.[^18]
- **PO notes and vendor communications**: Vendor interactions — confirmations, revision requests, exception resolutions — should be logged against the PO so any team member can reconstruct the conversation without digging through email.

Domain 5: Financial Footprint

ERP is not just operations — it must carry enough financial data to power decision-making and integrate with accounting:[9][2]

- **Order economics**: At minimum, every order must carry sell price, cost price, and the margin between them — at the line item level, not just the order total. This is the foundation of gross margin analysis.
- **Landed cost**: In furniture, the vendor's invoice price is only part of the actual cost. Ocean freight, customs duties, broker fees, port charges, inland freight, and receiving labor all stack on top. A proper ERP tracks these components and allocates them to product cost. Without this, every margin report is understated.[^2]
- **Invoicing**: The ERP must generate customer invoices tied to fulfilled orders and vendor invoices tied to received POs. Invoice records must reference the originating order and be exportable to accounting systems.
- **Accounts Receivable hooks**: B2B terms create AR exposure. The ERP must track what's been invoiced vs. paid, aging of outstanding balances, and credit utilization per account.[^19]
- **PCI-sensitive payment data**: B2B furniture orders often involve large-dollar credit card transactions. The ERP must either tokenize card data or strictly isolate it from general operations access. Cardholder data (card number, expiry, name, gateway IDs) must never surface in operational queries or agent responses.[^20]
- **Order ledger / financial audit trail**: Every financial event — charge, credit, adjustment, refund — should post to a ledger tied to the originating order. This creates the audit trail required for financial review and dispute resolution.

Domain 6: Operations, CRM & Communication Log

In a B2B operation, the order record is also a relationship record:[^21]

- **Rep activity log**: Sales reps and operations staff interact with orders constantly — calling vendors for updates, contacting customers about delays, escalating problems. These interactions must be logged against the order with timestamp, rep identity, and note type. Without this log, institutional knowledge lives only in email inboxes and people's heads.
- **Note taxonomy**: Not all notes are equal. A tracking update is different from a vendor communication, which is different from a customer complaint. Typed notes with category classifications let teams filter to what matters — and let future AI systems train on structured operational knowledge.
- **Email log**: Outbound emails to customers tied to orders should be logged so any rep can see what was communicated, when, and by whom. This prevents duplicate outreach and supports dispute resolution.
- **Automated status alerting**: The ERP should proactively surface exceptions — pending orders not acted on, orders on hold for payment, hot/priority orders needing attention — via daily reports or dashboards.

Domain 7: Reporting & Analytics

The ERP's data is only valuable if it can be queried and reported:[15][11]

- **Order book and backlog**: What orders are open, by status, by vendor, by rep, by age? What's at risk of missing a promise date?
- **Vendor performance report**: Which vendors are consistently late? Which have the widest gap between promised and actual ship dates?
- **Margin by line**: What is the gross margin on each order line, accounting for sell price minus landed cost? Which product categories, vendors, or customers are dragging margin?
- **Lateship tracking**: Furniture's most common operational failure — goods that ship later than the vendor originally committed. A lateship report identifies which open orders are past their original promise date.
- **Sales velocity and bestseller tracking**: Which items are selling fastest? What's the replenishment signal? These reports feed purchasing decisions.
- **Daily operational email reports**: In a high-volume operation, automated daily exception emails are how operations staff stay ahead of problems without manually polling the database.

Part 2: How E2GO's Custom SQL System Implements ERP

The e2go system is not a branded ERP product (no SAP, NetSuite, or D365 module is named as the core). Instead, it is a **purpose-built ERP-equivalent stack** implemented directly on Microsoft SQL Server on-premises, organized into three primary business databases. This is actually common for established specialty retailers who outgrew generic ERPs or predated accessible cloud SaaS — they built the system themselves, and it now carries a decade of operational data and business logic.[^20]

Database Architecture Overview

Database	ERP Domain	Scale
`e2go_Order`	Orders, customers, fulfillment, POs, invoices, notes, ledger	58 tables; CustomerOrder ~310K, Notes ~1.93M[^20]
`e2go_Item`	Product catalog, SKUs, pricing, vendors, images, attributes, lead times	95 tables; Item ~124K, ItemOption ~686K[^20]
`e2go_Company`	Employees, email system, geo reference	16 tables; Email ~2M[^20]
`e2go_Navigation`	Website catalog projections, display tags	Separate DB, synced from Item[^22]
`e2go_Queue`	Event-driven email notification triggers	Separate DB, feeds e2go_Company email[^22]
`e2go_Import`	Vendor data import staging	Separate DB[^22]

Cross-database joins (e.g., `CustomerOrderDetail.ItemUID` → `e2go_Item.Item.ItemUID`) are performed at the application level — there are no enforced foreign key constraints between databases. This is a meaningful architectural decision: it gives each database schema independence but means integrity checks must live in application code, stored procedures, or ETL logic.[^20]

Customer & Commercial Order Coverage

The `CustomerOrder` table is the top-level record of commercial activity. It carries bill-to and ship-to as separate `CustomerUID` foreign keys into the `Customer` table, cleanly separating the financial relationship from the physical delivery address. The `Customer` table (~650K rows) is the persistent account master for all B2B buyers.[^20]

What's well-implemented:

- Bill-to / ship-to separation on every order[^20]
- Order source (`OrderSourceUID` → `OrderSource`), order type (`CustomerOrderTypeUID`), and website attribution flags[^23]
- Marketing attribution via `CustomerOrderReferrer`, `CustomerOrderReferenceCode`, and `ReferenceCode2` — linkable to GA4 and CallRail[^20]
- Quote records: `CustomerQuote` (~21K), `CustomerQuoteDetail` (~78K), `CustomerQuoteNote` (~53K) — the full quote-to-order chain exists[^20]
- Tax exemption: `TaxExemptCustomer` (~21K rows) — B2B exempt accounts are tracked[^20]

- Payment status: `CustomerOrder` carries `paid_in_full` flag, accessible as a search filter in the MCP tool[^23]

What's present but requires scrutiny:

- Credit terms and pricing tier logic — not visible in the schema inspection. These are likely implemented in application-layer code or stored procedures (28 SPs exist but are not viewable with current credentials). The `VendorPricing` table in `e2go_Item` suggests tiered pricing exists at the catalog level.[^22]
- AR aging — `OrderLedger` (~488K rows) exists and likely covers financial posting events, but the schema of this table wasn't fully exposed.[^20]

Product Catalog Coverage

The `e2go_Item` database is a full Product Information Management (PIM) system:[^20]

- **Item master** (`Item`, ~124K): Each item carries `ItemNumber` (the rep-facing lookup key), vendor linkage, collection grouping, status, and pricing fields[23][20]
- **SKU variants** (`ItemOption`, ~686K): Each combination of color/finish/size/configuration is a distinct `ItemOption` with its own `ItemOptionSKU`, customer-facing description, and availability flag[^20]
- **Lead times** (`ItemLeadTime`, ~986K): Lead time records exist at a granular level, joinable via `LeadTimeType` for min/max lead time reporting per SKU[^23]
- **Colors** (`Color`): A color dimension table for display and cross-sell logic[^23]
- **Images** (`ItemImages`, ~1.15M): Rich product image data at scale[^20]
- **Attribute values** (`ItemAttributeValues`, ~2.06M): Specification data (dimensions, materials, etc.) at very high volume[^20]
- **Collections** (`VendorCollection`, `ItemVendorCollections`): Vendor-level collection groupings enabling cross-sell recommendations within a collection and color[^23]
- **Availability signals**: `Item` carries stock/availability flags and `ItemEstimateInStockDate` — the back-in-stock date for lateships[22][23]
- **Vendors** (`Vendor`, ~781 rows): Full supplier master in the Item database, linked from both catalog and order records[^23]

The `e2go_Navigation` database is a projection layer — it maintains materialized views of the Item catalog optimized for website display (item type trees, display tags, category/collection structures). This is a healthy architectural pattern: the operational catalog lives in `e2go_Item`, and the website-facing read model lives in `e2go_Navigation`, synced by scheduled SQL Agent jobs.[^22]

Multi-Vendor Fulfillment Coverage

This is where the e2go system most clearly demonstrates its furniture-industry specialization. The `e2go_Order` database implements a three-layer fulfillment hierarchy:[23][20]

```
CustomerOrder (header, ~310K)
  └── VendorOrder (one per vendor per order, ~349K)
        └── VendorOrderDetail (line items per vendor, ~478K)
```

This maps precisely to the ideal model described in Part 1. Each `VendorOrder` represents one vendor's commitment within the customer's order, with its own status (8 statuses per `VendorOrderStatus`), its own ship dates (calculated, actual, promise, revised, estimated), and a completion flag.[16][13] [^23]

`VendorOrderDetail` carries the full pricing decomposition per line: sell price, cost, list price, merchandising price, freight, delivered price, and surcharge. This is the cost stack visibility that proper margin analysis requires.[^23]

Purchase Order chain is fully implemented:[^23]

```
VendorOrder → VendorPO (~235K) → VendorPODetail (~347K)
```

`VendorPONote` (~204K rows) stores vendor communications against each PO — vendor confirmations, revision requests, exception discussions. The `fnExtractTrackingNumberFromNote` and `fnExtractCarrierFromNote` functions in `e2go_Order` parse tracking and carrier data from note text fields, indicating that tracking information flows through the notes system rather than dedicated structured columns.[22][20]

Delivery date revision tracking exists as `DeliveryDatesHistory` (~544K rows). This is the audit trail for ship date changes — start date and end date per revision per `VendorOrderDetail` line. This is exactly the data needed to calculate vendor lead time reliability and lateship attribution.[^20]

Exception alerting is implemented via 22 automated SQL Agent job steps that fire daily emails. The operational exceptions covered include:[^22]

- Invoices missing ship dates
- Open orders without POs (orders confirmed but no PO issued to vendor)
- Orders missing tracking after 120 days
- Pending orders and pending routing-review orders
- Hold-for-payment orders
- White Glove / W2 delivery orders requiring special handling
- Alaska and Hawaii orders (freight complexity flag)[^22]

`VendorReplacementOrder` (~7K rows) handles the replacement order workflow when damaged or incorrect goods must be re-ordered from a vendor.[^20]

Financial Footprint Coverage

The financial layer is present but partially visible:

- **Order economics**: `VendorOrderDetail` carries sell, cost, list, merch, freight, delivered, and surcharge prices — this is a multi-layer cost stack, not just a single cost field.[^23]
- **Vendor invoices**: `VendorOrderInvoice` (~490K rows) tracks vendor-side billing events tied to vendor orders.[^20]
- **Order ledger**: `OrderLedger` (~488K rows) — a financial ledger tied to orders. The schema wasn't fully inspected but this is the likely home for charge/credit/adjustment posting.[^20]
- **Customer invoices**: Referenced in the architecture but the invoice table structure appears to be tied to `VendorOrderInvoice` rather than a separate customer AR table — worth clarifying.
- **SSRS reporting**: A SQL Server Reporting Services instance exists with five installed reports: Landed Gross Margin Report (two versions), Lateship Report, Orders By Day, and Purchase Order Report. These are exactly the reports a furniture ERP would be expected to produce, confirming that financial and operational reporting was designed into the system.[^22]
- **PCI isolation**: Credit card fields on `CustomerOrder` (`CustomerOrderCreditCardNumber`, `CustomerOrderCreditCardExpirationDate`, `CustomerOrderCreditCardName`, Authorize.Net transaction IDs) are excluded from all MCP tool SELECT lists by policy. The data exists but is not exposed through any agent-accessible path.[^20]

Gap: Full AR aging (Days Sales Outstanding, open balance by account) is not clearly surfaced in the inspected schema. The `OrderLedger` likely contains the raw data, but a clean AR report would require verified schema inspection.

Operational CRM & Notes Coverage

The `CustomerOrderNote` table at ~1.93M rows is one of the most functionally rich elements in the system. This is where reps actually work: every vendor call, tracking update, customer inquiry, and escalation gets a note entry. The architecture document explicitly calls this "the primary record of rep activity" and notes that reps work in these notes all day.[23][20]

The notes system is fully typed — `CustomerOrderNoteType` has 18 categories (tracking, general, vendor communication, etc.). Notes carry a pinned flag, a deleted flag (soft delete), an owner field (rep name), a timestamp, and a vendor code associating notes to specific vendors on multi-vendor orders.[^23]

`CustomerOrderCancellationHistory` (~11K rows) preserves the reason and context for every cancellation — important both for operations and for training AI models on exception handling.[^20]

The `EmailLog` (~796K rows) records outbound emails sent from the CRM, and `e2go_Company.Email` (~2M rows) is a full email archive. Employee records carry per-brand

HTML email signatures (`SignatureE2go`, `SignatureOF2go`, `SignatureBestar2go`, etc.), enabling brand-appropriate communications.[^20]

Automated status changes are tracked in `OrderStatusChange` (~344K rows) — every status transition on a customer order is recorded with old status, new status, and timestamp. This is the audit trail that lets any team member reconstruct the full history of an order's lifecycle.[^20]

Reporting & Automation Coverage

The SQL Agent job system runs 22 steps daily, including:[^22]

Report/Alert	What It Covers
DailyOrdersTotalReport	Full daily order volume
DailyOrdersScore45Report	High-score (priority) orders >$500
Lateship Back in Stock?	Items with `ItemEstimateInStockDate = today`
Orders without Tracking (>120 days)	Fulfillment exception monitoring
Customer Orders without POs	Orders confirmed but PO not yet issued
Vendor Invoices for QuickBooks	Daily CSV export to accounting
ListItemsEditedPreviousDay	Catalog change audit
Replenish date = today	Inventory replenishment signal
Hold for Payment orders	AR / credit hold monitoring
Hot Orders	Priority order view (`vwHotOrders`)

The QuickBooks export confirms that the system is **not self-contained for accounting** — financial data flows out to a separate accounting package. This is the typical "ERP + accounting" integration pattern where the operational ERP handles order economics and the accounting system handles general ledger, bank reconciliation, and tax filing.

Part 3: Gap Analysis — What the Ideal Expects vs. What E2GO Has

ERP Domain	What the Ideal Expects	What E2GO Has	Gap Assessment
Customer master	Persistent B2B accounts, history, credit	`Customer` (650K), bill-to/ship-to separation	✅ Covered
Pricing tiers	Account/volume-based pricing	`VendorPricing` table exists; app-layer logic unclear	⚠️ Partially visible
Credit terms	Net 30/60/90, credit limits, AR aging	`OrderLedger` + QuickBooks export; AR aging unclear	⚠️ Partially covered
Quote → Order	Preserve quote through order conversion	`CustomerQuote` / `CustomerQuoteDetail` / `CustomerQuoteNote`	✅ Covered

ERP Domain	What the Ideal Expects	What E2GO Has	Gap Assessment
Tax exemption	Per-account tax-exempt certs	`TaxExemptCustomer` (21K rows)	✅ Covered
Item/SKU hierarchy	Parent item + variant axes	`Item` + `ItemOption` (686K SKUs)	✅ Covered
Lead times per SKU	SKU-level lead time min/max	`ItemLeadTime` (986K), `LeadTimeType`	✅ Covered
Multi-vendor order split	Automatic vendor-level grouping	`VendorOrder` + `VendorOrderDetail`	✅ Covered
PO generation	PO per vendor from customer order	`VendorPO` + `VendorPODetail` (235K / 347K)	✅ Covered
Ship date revisions	Full revision history per line	`DeliveryDatesHistory` (544K)	✅ Covered
Vendor performance	On-time %, lateship attribution	Data exists; `spVendor_UpdateVendorRanks` SP exists	✅ Data present; SP obscured
Freight / delivery types	White glove, inside, accessorials	White Glove flag in daily alerts; `DeliveryType` table	✅ Partially covered
Order lifecycle audit	Full status history with timestamps	`OrderStatusChange` (344K)	✅ Covered
Rep notes / activity log	Typed, categorized, searchable notes	`CustomerOrderNote` (1.93M, 18 types)	✅ Richly covered
Landed cost	FOB + freight + duties + port charges	Vendor line freight field; no explicit landed cost table visible	⚠ Partial — may need dedicated cost layer
Container management	Container tracking, in-transit visibility	Not visible in schema; may be external	❌ Gap (if importing direct)
Full AR module	Invoice aging, credit limit enforcement	QuickBooks integration; `OrderLedger` exists	⚠ Offloaded to accounting
Product availability ATP	Real-time available-to-promise	Non-authoritative signals only; no warehouse ATP	⚠ Known limitation (documented)
Demand forecasting	Forward-looking purchasing signals	`MostSoldItems` cache, bestseller views exist	⚠ Basic; no statistical forecast
Dimensional management	Length/width/height, cube, stackability	`ItemAttributeValues` (2M+ rows) carry specs	✅ Attributes exist; cube calc unclear
PCI isolation	Card data never exposed in operations	All card columns excluded from MCP tools by policy	✅ Implemented by exclusion
SSRS/reporting	Margin, lateship, PO, backlog reports	5 SSRS reports + 22 daily SQL Agent email reports	✅ Covered for core needs

Part 4: Structural Observations

Strength: The Operational Depth Is Exceptional

With ~310K orders, 1.93M notes, 544K delivery date revisions, and 344K status changes, this is not a lightweight system — it is a production ERP that has processed years of real B2B furniture transactions at meaningful scale. The note corpus alone represents an extraordinary institutional knowledge asset that most ERPs do not come close to capturing.[^20]

Strength: The Fulfillment Model Is Exactly Right for Furniture Dropship

The three-layer `CustomerOrder → VendorOrder → VendorPO` architecture is precisely the correct model for a multi-vendor dropship operation. Many generic ERPs implement only a flat "order → PO" model. This system's explicit vendor-grouping layer (VendorOrder) means that every vendor gets a clean, independent view of their work within a customer order — enabling proper status tracking, pricing separation (cost vs. sell), and PO generation per vendor.[16][20]

Structural Risk: No Cross-Database Foreign Keys

The application-level joins across the three databases mean that referential integrity is enforced in code, not in the database engine. This is acceptable when the application is the only writer, but it creates risk if data is loaded via imports, bulk updates, or external tools that bypass application validation. Orphaned records (e.g., `CustomerOrderDetail.ItemUID` pointing to a deleted `Item`) would be silently incorrect rather than rejected.[^20]

Structural Risk: Business Logic in Stored Procedures

28 stored procedures exist that are not inspectable with current read credentials. These procedures contain business logic — pricing rules, rank calculations, status transitions — that is effectively invisible to anyone building on top of the system without DBA access. For an AI agent layer or any new integration, understanding this hidden logic is critical to avoiding conflicts with existing automation.[^22]

Opportunity: The Notes Corpus as AI Training Data

The 1.93M notes in `CustomerOrderNote` represent a decade of how this specific operation handles exceptions, communicates with vendors, and resolves customer issues. With proper filtering (`CustomerOrderNoteDeleted = 0`, note type classification), this corpus could train or fine-tune domain-specific language models for tasks like automated vendor inquiry drafting, exception triage, or customer status responses — a capability that no off-the-shelf ERP can offer without years of operational data accumulation.[^20]

Integration Pattern: ERP + QuickBooks

The daily QuickBooks CSV export confirms this is an **ERP + accounting** architecture, not a fully integrated financial system. The e2go system owns the operational record (orders, fulfillment, vendor invoicing); QuickBooks owns the books (general ledger, bank reconciliation, payroll, tax). This is a common and defensible pattern for mid-market operations, but it means the authoritative margin calculation must reconcile across both systems — any discrepancy between `OrderLedger` and QuickBooks represents a reconciliation risk.[^22]
